Optimization-FAQ's

Multivariate Optimization

1. In the lecture on Multivariate Optimization with Equality Constraints, In example $3x_1 + 2x_2 - 12 = 0$, how to get the following values for x_1 and x_2 ?

Answer:

$$-4x_1 - 3\lambda = 0 \rightarrow (1)$$

$$-8x_2 - 2\lambda = 0 \rightarrow (2)$$

$$3x_1 + 2x_2 - 12 = 0 \rightarrow (3)$$

$$(1) * 3 \Rightarrow -12x_1 + 0x_2 - 3\lambda = 0 \rightarrow (4)$$

$$(3) * 4 \Rightarrow 12x_1 + 8x_2 + 0\lambda = 48 \rightarrow (5)$$

$$(4) + (5) \Rightarrow 8x_2 - 9\lambda = 48 \rightarrow (6)$$

Solving (6) and (2)

$$(6) + (2) \Rightarrow -11\lambda = 48$$

$$\lambda = -\frac{48}{11}$$

Substituting λ value in (1) to find x_1

$$-4x_1 - 3\left(-\frac{48}{11}\right) = 0$$

$$-4x_1 = -\frac{144}{11}$$

$$4x_1 = 13.09$$

$$x_1 = \frac{13.09}{4} = 3.2725$$

Substituting λ value in (2) to find x_2

$$-8x_2 - 2\left(-\frac{48}{11}\right) = 0$$

$$-8x_2 = -\frac{96}{11}$$

$$8x_2 = 8.72$$

$$x_2 = 1.09$$

2. How will we get the values of x_1^* and x_2^* and the second derivative λ_1 and λ_2 in the below slide (Multivariate optimization)?

Multivariate optimization - Numerical example

Multivariate optimization

min $x_1 + 2x_2 + 4x_1^2 - x_1x_2 + 2x_2^2$

First order condition	Second order condition
$\nabla f = \begin{bmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \end{bmatrix} = \begin{bmatrix} 1 + 8x_1 - x_2 \\ 2 - x_1 + 4x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$	$\nabla^2 f = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} \end{bmatrix} = \begin{bmatrix} 8 & -1 \\ -1 & 4 \end{bmatrix}$
$\begin{bmatrix} x_1^* \\ x_2^* \end{bmatrix} = \begin{bmatrix} -0.19 \\ -0.54 \end{bmatrix}$	$\begin{bmatrix} \lambda_1 \\ \lambda_2 \end{bmatrix} = \begin{bmatrix} 3.76 \\ 8.23 \end{bmatrix}$

Optimization

that what I have to do is I have to do this

Answer:

Solve the two equations

$$8x_1 - x_2 = -1 \rightarrow (1)$$

$$-x_1 + 4x_2 = -2 \rightarrow (2)$$

Multiply the (2nd) equation by 8

$$x_2 = -17/31 = -0.54$$

Substitute the value of x_2 in any one of the equation and get the x_1 value.

λ_1 and λ_2 are the eigen values of the hessian matrix.

Enter the 2*2 matrix in R and use `eigen(matrix_name)`, you will be able to get the values of λ .

Stationary points

1. What is a stationary point for a function?

Answer:

For $f(x)$,

Solution of $\text{grad}(f) = 0$ in case of multivariate optimization problem

Solution of $f'(x) = 0$ in case of univariate optimization problem

Unconstrained Multivariate Optimization

1. In the lectures on Unconstrained Multivariate Optimization, why have we taken the negative of gradient for search direction while calculating the $f(x)$.

Answer:

Searching requires an objective. Let's assume this objective is minimization of F . Then, from where we are (epoch n), we need to get a lower value (epoch $n+1$). On the other hand, numerically, the gradient can be thought of as the ratio of change in F when x is increased. This ratio can be positive (F increases with x) or negative (F decreases with increase in x).

For simplicity, assume the positive gradient case with learning rate of unity. A lower value of F is required in order to minimize. One then needs to subtract the gradient from current epoch value so that the value is minimized. Adding the gradient will only make F larger and is of no use for minimization. Hence the negative sign for the gradient.

If the gradient is zero, there are no more epochs to improve upon, so the search is stopped.
